

radical halogenation of alkanes

<p>reaction type: radical substitution</p>
<p>reaction:</p> $\begin{array}{c} \\ -\text{C}-\text{H} \\ \end{array} + \text{X}-\text{X} \xrightarrow{\Delta \text{ or } h\nu} \begin{array}{c} \\ -\text{C}-\text{X} \\ \end{array} + \text{H}-\text{X}$ <p>X = F, Br, or Cl</p>
<p>mechanism: (radical chain)</p> <p>initiation (nonradical → 2 radicals):</p> $\text{X}-\text{X} \xrightarrow{\Delta \text{ or } h\nu} 2 \text{X}\cdot$ <p>propagation (radical + nonradical → radical + nonradical):</p> <p>Propagation step one (rate-determining step)</p> $\begin{array}{c} \\ -\text{C}-\text{H} \\ \end{array} + \text{X}\cdot \rightarrow \begin{array}{c} \\ \cdot\text{C} \\ \end{array} + \text{HX}$ <p>Propagation step two</p> $\begin{array}{c} \\ \cdot\text{C} \\ \end{array} + \text{X}-\text{X} \rightarrow \begin{array}{c} \\ -\text{C}-\text{X} \\ \end{array} + \text{X}\cdot$ <p>termination (2 radicals → nonradical):</p> $\begin{array}{c} \\ \cdot\text{C} \\ \end{array} + \text{X}\cdot \rightarrow \begin{array}{c} \\ -\text{C}-\text{X} \\ \end{array}$ $\text{X}\cdot + \text{X}\cdot \rightarrow \text{X}-\text{X}$ $\begin{array}{c} \\ \cdot\text{C} \\ \end{array} + \begin{array}{c} \\ \cdot\text{C} \\ \end{array} \rightarrow \begin{array}{c} \quad \\ -\text{C}-\text{C}- \\ \quad \end{array}$
<p>regiochemistry:</p> <p>For fluorine, which is highly reactive and thus unselective, “statistics” dominates, and the major product usually comes from abstracting the type of hydrogen in greatest abundance.</p> <p>For bromine, which is less reactive and thus more selective, “electronics” dominates; the major product comes from abstracting the hydrogens on the most substituted carbon.</p> <p>For chlorine, with intermediate reactivity and selectivity, the major product is calculated using chlorine’s selectivity ratio (3°:2°:1° = 5:4:1) and the statistical ratio of the hydrogens.</p>
<p>stereochemistry: maximum of two stereoisomers, in equal amounts (because the carbon-radical intermediate is trigonal planar)</p>
<p>synthetic usefulness: Radical halogenation is useful for introducing a functional group into a non-functionalized molecule.</p> <p>Bromination is most useful for synthesis because it is highly selective for the hydrogens on the most substituted carbon. Because chlorine and fluorine are less selective, they tend to give a mix of products and thus are less useful for synthesis.</p>
