

## effect of full or formal charges on reactivity

location of charge	reactivity	arrow-pushing
$\overset{\ominus}{\text{X}}$ 	X is nucleophilic or basic	
$\overset{\ominus}{\text{X}}-\text{Y}$ no lone pairs	Y is nucleophilic or basic	
$\overset{\oplus}{\text{X}}$ incomplete octet (carbocation)	X is electrophilic	
$\overset{\oplus}{\text{X}}-\text{Y}$ complete octet (non-carbocation)	Y is electrophilic or an acidic hydrogen and X is a good leaving group	

Metals with positive charges are spectator ions, not electrophiles or leaving groups.

Watch out for resonance, for two reasons: (1) Resonance-stabilized charges are less reactive than without resonance-stabilization. (2) Drawing alternative resonance structures will indicate alternative reactive atoms by shifting the charges.

## reactivity without full or formal charges

nucleophile or base	electrophile or acidic hydrogen
nonhalogen with lone pair(s)	atom with $\delta^+$ and ... good leaving group
carbon with $\delta^-$ (tail on sigma bond)	... or pi bond
carbon-carbon pi bonds	... or incomplete octet
	$\text{Cl}_2$ or $\text{Br}_2$ reacting with carbon-carbon pi bond

Atoms that satisfy these conditions are *candidates* for reactivity. They may still not be reactive enough, or may not be appropriate in some other way, for particular reactions.

## when to form or break covalent bonds

<b>break a covalent bond when...</b>	...it's at the tail of an electron-pushing arrow. <i>Do NOT break any covalent bond that is not at the tail of an arrow.</i>
<b>form a <math>\sigma</math> bond when...</b>	...the arrow head is pointing to an atom which is not already sharing the electrons represented by the arrow
<b>form a <math>\pi</math> bond when...</b>	...the arrow head is pointing to a bond

## when to form or break ionic bonds

<b>break the ionic bond between two atoms when...</b>	...one of the atoms has lost its charge
<b>form an ionic bond between...</b>	...a spectator ion and an atom that has gained a charge

Ionic bonds are represented simply by drawing two charged atoms close to each other.
